Abstract

This Checklist of Supernovae in the NGC and IC Galaxies Through 1985 is presented to assist those interested in undertaking a visual or photographic search for extragalactic supernovae. Some galaxies appear to have had more than one or two supernovae, and these should be monitored closely for any new outbursts.

* * * * *

1. Introduction

Various sources were used in this compilation, which is as complete as possible. This list is not intended to replace any general authoritative listing and is a guide only. Any errors or omissions, therefore, should be reported to the author, as it is hoped that a new list will be compiled from time to time.

For supernovae prior to 1976 the **General Catalogue of Variable Stars** (Kukarkin et al. 1969) (GCVS) and **Supplements** (Kukarkin et al. 1971; 1974; 1976) were consulted. After 1975 (December) the **IAU Circulars** as edited by Marsden were used.

2. Description of Format

1. **NGC** = The standard number from the **New General Catalogue of Nebulae and Clusters of Stars** (Dreyer 1888).

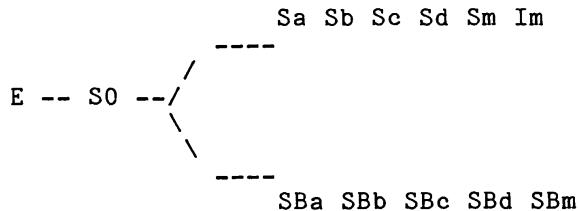

2. **IC** = The number in the **Index Catalogue** (Dreyer 1895) and the **Second Index Catalogue** (Dreyer 1908), with additional references by Sulentic and Tifft (1977).

3. **OTHER?** = Other designations as in the following example:
 M31 - The number in the catalogue of Charles Messier (Becvar 1960).

4. **GALAXY TYPE** = Galaxy types were obtained primarily from **A Revised Shapley-Ames Catalog of Bright Galaxies** (Sandage and Tamman 1981).

For an extensive review of the classification of galaxies, other references should be consulted, as certain precepts are set down by various authorities and are beyond the scope of this listing.

However, the following classification may be represented:

with intermediate classes (S0/a, etc.) (after Sandage 1961). The new class "Amorphous" which replaces "Irr" (Sandage and Brucato 1979) has

not been retained, as it is felt to be too ambiguous for this paper. Some galaxies, mainly spirals, are represented by a simple S as a definite designation has not been given in the available texts consulted.

Descriptive terms, such as "Pec" (= peculiar), have been added where necessary.

Barred spirals are designated SB, intermediate type S/SB with the normal spiral having arms that curve out directly from the rounded condensed center. In a barred spiral these arms begins at opposite ends of a flattened oblong central bar.

To the primary letter S or SB is appended one of four small letters, a, b, c, or d. These serve to further differentiate among the various sub-classes. In an "a" system the central bulge appears to dominate the general structure if the galaxy, giving rise to tightly-wound narrow arms. In a "b" system the central bulge and spiral arms appear equally prominent. In a "c" system the spiral arms are widely opened and well-resolved into clumps and clouds of stars. The fourth sub-class, "d," is used to designate a tiny central condensation of the center, giving an almost stellar appearance. In this sub-class, the spiral nature is hard to distinguish from the star clouds throughout the system.

The existence of an inner ring structure is further indicated by "(r)." Again there is a further sub-class denoted by "(s)" to indicate spirals whose arms spring from the ends of the bar or can be traced to the center. Intermediate types are again present and are denoted by "(rs)." To further complicate matters, any outer rings are indicated by an R preceding the type (see NGC 6217).

The E and S0 galaxies are classified according to their flattening (Sandage 1961). The further subdivision of S0 galaxies into S01, S02, etc., according to their dust content is by Sandage (1961). The subdivision of barred spirals into SB01, SB02, etc., should not, however, be confused with the classes just described, as the 01, 02, etc., refer to the character of the bar and not to the presence of dust (Sandage 1961).

The I or IRR systems are irregular galaxies which appear as coarse masses of star clouds without any definite structure. Some of these, however, may grade into coarse spirals as some appear to show a weak spiral pattern.

Additional information on classifying galaxies may be obtained from de Vaucouleurs (1964; 1977) or Zwicky *et al.* (1961-68).

As this list indicates, supernovae are prominent in the S-type galaxies, especially the Sc and Sb types.

5. YEAR[S] = The year the supernova was found. In most cases the same year the outburst actually occurred (but not always).

6. SUPER MAG = The supernova magnitude, taken from various published authorities and noted as "v" (visual), "p" (photovisual), "pg" (photographic), and "B" (B on the **UBV** system).

7. GAL MAG = The magnitude estimate for the galaxy, obtained from **Burnham's Celestial Handbook**, Volumes 1, 2, and 3 (Burnham 1978), with occasional reference to **Atlas Coeli II - Katalog 1950.0** (Becvar 1960). Unless otherwise stated the magnitude estimates are visual.

8. IAUC[S] = The **IAU Circulars**, referenced from December, 1975, to January, 1986.

3. Additional Comments

The actual listing was compiled using a COMPAQ computer running MS-DOS version 2.11. The software is a PC-FILE III version 1.0. If so desired, the author will supply the data on a properly formatted diskette accompanied by a large self-addressed mailer (stamped if requested from Canada; postage funds included otherwise). Please note, however, that the actual program is not available. It may be obtained from the software developer.

4. Conclusion

The AAVSO has had a regular supernovae search program and is currently developing field charts for specific galaxies. This listing should encourage observers to undertake a systematic check of likely candidates for supernovae.
